

ENTaP Honey Economy Constitution v2

Revision Summary

This document captures the design decisions made after Version 1 regarding Honey distribution philosophy, tier scaling, pricing methodology, Hive economics, and anti-inflation principles.

Hive Honey Model

Version 1 Hive spending remains unchanged. Every player's Honey remains their own and follows them if they leave a Hive. A Hive's purchasing power is simply the sum of the Honey held by all current members.

When Hive leadership approves a purchase, every member contributes automatically in proportion to their current Honey balance. Every member sacrifices the same percentage of their holdings, making the system simple, transparent, and fair.

Before any Hive purchase is finalized, every member should be able to see exactly how much Honey will be deducted from their balance.

Recruitment Philosophy

Players are encouraged to join Hives because Honey is significantly more useful inside a Hive than outside one. This replaces artificial incentives for joining.

Recruitment packages should unlock over time to prevent 'join, collect, leave' behavior. Rewards should vest over days or weeks rather than immediately.

Economic Philosophy

Honey is not balanced around individual grinding. It is balanced around enabling Hives to make meaningful collective investments.

Money games should reward more Honey than free games, but the difference should accelerate progress rather than make free players feel irrelevant.

Honey should remain a compact, meaningful currency. A single Honey should always feel valuable.

Reward Tier Structure

The economy will use exponential base tiers rather than linear tiers. The base tier establishes the reward band, while individual activities within the tier can vary upward without changing the tier relationships.

Base Reward Ladder

Community: 1 Honey
Engagement: 2 Honey
Competitive Participation: 4 Honey
Competitive Success: 8 Honey
Platform Growth: 16 Honey

These values represent base rewards only. Individual activities within each tier may award higher values while remaining inside their tier's reward band.

Pricing Methodology

Item prices will NOT determine reward values. Instead, reward ratios are established first. Once the complete activity list is organized into tiers, item prices will be derived from those reward rates and the desired amount of player effort required to obtain them.

The goal is to preserve Honey's value while allowing meaningful progression toward Hive investments.

Competitive Economy Decisions

Paid competitive activities should always reward more Honey than equivalent free activities because they provide greater value to the platform.

However, the difference should remain moderate so that free players continue to feel they are making meaningful progress.

Competitive prestige should come primarily from stronger competition, rankings, tournaments, and prize pools—not from runaway Honey rewards.

Anti-Inflation Principles

- Keep Honey values intentionally small.
- Preserve the perceived value of earning one Honey.
- Avoid large numerical inflation over time.
- Compress reward ranges so the highest repeatable rewards remain within a reasonable multiple of the lowest repeatable rewards.
- Allow growth through better activities rather than exponentially larger numbers.

Open Balance Work

- Populate every activity within each reward tier.
- Determine reward ranges inside each tier.
- Price Hive cosmetics, recruitment packages, buff packs, tournament entries, and prestige items using the established reward ladder.
- Balance earn rates using expected player activity rather than arbitrary currency totals.
